☁ Weather App – Project Summary

This is a simple desktop weather application built using Python's Tkinter library. It allows users to select an Indian state or union territory from a dropdown menu and retrieve real-time weather data such as:

🌥 Weather Condition (e.g., Clear, Rainy)

≋ Climate Description (e.g., light rain, overcast clouds)

🌡 Temperature in Celsius

🎐 Atmospheric Pressure

The app fetches this data from an online weather API using the requests module and displays the results in a clean and user-friendly GUI. It's a great project demonstrating how to work with APIs, handle GUI layouts, and build responsive apps in Python.
